

To accomplish this, we can begin by adding a **Shuffle!** button to our HTML template:

```
<div id="app" class="columns">
  <div class="column">
    <button class="is-primary button" @click="shuffle">Shuffle!</button>
    <tweet-component v-for="tweet in tweets" :tweet="tweet"/>
  </div>
</div>
```

Adding Shuffle

We've added a **@click** event listener to the button, which when activated, initiates a shuffle process. We'll create the shuffle method in our Vue case, which will be responsible for randomly shuffling the tweets collection in the instance. To execute this, we'll use lodash's **_shuffle** method:

```
new Vue({
  el: '#app',
  data: {
    tweets
  },
  methods: {
    shuffle() {
      this.tweets = _.shuffle(this.tweets)
    }
  }
});
```

Addition of click

Vue would not generate special bindings for each tweet node since we did not use the main attribute. As a consequence, when reordering the tweets, Vue takes the more efficient method of simply changing (or patching) the data in each element. Because the temporary DOM state (i.e., the inputted text) is retained, this unintentional mismatch occurs.
