

scroll down the list, infinite scroll adds data to the end of the tab. Just a portion of the data is accessed as the page first loads. More information is added when you move down the list.

Conclusion

A popular method to view a list of data is to create a list in the browser. This is very different from how you would address this with one of the other common UI frameworks, such as Vue or Angular. In some other frameworks, you will iterate directly in HTML using personalized directives such as **v-for** or **ng-for**. With the response, iteration is accomplished by the use of native JavaScript. Thus, in React, you can iterate over an array and generate a list using the **map()** method. Although React lacks the syntactic sugar of **ng-for** or **v-for**, we can achieve the same impact using the JavaScript map function. To update objects in a made list, Vue employs an in-place patch strategy. Rather than recreating the list, Vue locates the object that was modified and changes it. This is significantly faster than recreating and rendering the list.
