

Component Communication: Props in, Events out

Rip Tutorial

Events

Events are a great way to build interactivity in your web applications

Introduction

Events or occurrences arise in the machine you're programming, which the system informs you of so you can react accordingly. If a user clicks a button on a website, for example, you may want to answer by showing an information box.

When an incident happens in the system you're programming, the system emits (or "fires") a signal of some sort and creates a trigger for a response to be taken immediately (that is, a code to run).
