

This is a clear illustration of how to show and hide a **<div>** with a video feature inside it:

The video is shown when the **<button>** is clicked by modifying the class attribute on the **<div>** from **secret** to **displaying** (the example's CSS includes these two classes, which places the box off the screen and on the screen, respectively):

```
btn.onclick = function() {
  videoBox.setAttribute('class', 'showing');
}
```

Using <div>

After that, we add two more **onclick** event handlers, one to the **<div>** and the other to the **<video>**. The box can now be covered when the area of the **<div>** outside the video is chosen, and when the video itself is selected, the video should begin to play.

```
videoBox.onclick = function() {
  videoBox.setAttribute('class', 'hidden');
};

video.onclick = function() {
  video.play();
};
```

Using <div>

However, there is a problem: when you pick the film, it begins to play, but the **<div>** is obscured at the same time. Since the video is contained inside the **<div>** — it is a part of it — clicking it activates any of the above event handlers.

## Bubbling and capturing described

Modern browsers operate two stages while an event is shot on an element with parent elements (in this instance, the **<video>** has the **<div>** as a parent), the capturing process and the bubbling phase.
