

be done to fix it. While certain browsers have automated type data validation capabilities, many do not, so you should not focus on them and instead perform your own validation tests. Let's take a peek at a simple scenario.

To begin, fill out the HTML form on the previous page with your first and last names.

Delegation of an event

Bubbling helps you to take advantage of event delegation, which is based around the idea that if you want any code to run while you pick each of a vast range of child components, you can set the event listener on their parent and make events that happen on them bubble up to their parent rather than trying to set the event listener on each child separately. Remember that bubbling means first looking for an event handler on the element where the event is shot, then going up to the element's parent, and so on.

If you want each list item to show up a notification when it is picked, you should set the click event listener on the parent `<ul>`, and events will bubble up from the list items to the `<ul>`.

Conclusion

At this stage, you should know everything there is to know about web events. As previously stated, events are specified in browser Web APIs and are not part of the core JavaScript.

Often, various event models are found in different environments where JavaScript is used, ranging from Web APIs to other fields such as browser WebExtensions and Node.js (server-side JavaScript). We don't expect you to grasp any of these concepts right away, but understanding the fundamentals of events can help you progress while you study web creation.

Another factor worth noting at this point is that events aren't special to JavaScript; most programming languages have an event model, but the way it operates varies from JavaScript. In reality, the event model for web pages in JavaScript varies from the event model for JavaScript in other environments.
