Browserify

Use the package.json for adding your projects.

- {
- // ...
- "browser": {
- "vue": "vue/dist/vue.common.js"
- }
- }
- Parcel
- Use package.json for adding it.
- {
- // ...
- "alias": {
- "vue" : "./node_modules/vue/dist/vue.common.js"
- }
- }

The difference between Development and Production Mode

The codes developed for the development and production modes of UMD builds are very strategic and robust. Thus, you can have minified files for production and un-minified files for development.

ES Modules and CommonJS are designed for bundlers. Thus, you would not find its smaller or minified versions. As a result, you will have to self-minify the final bundle.

For *process.env.NODE_ENV*, *ES Modules* and *CommonJS* builds take care of these raw checks. They help in identifying the mode that they can be developed to run in. You need to replace the variables for the environment with proper bundler configurations. This will help in controlling the mode of Vue. When the string literals replace *process.env.NODE_ENV*, they completely reduce the use of development-only code blocks while allowing minifiers such as UglifyJS. This influences the final file size.

Webpack

The mode option is available in Webpack 4+:

- module.exports = {
- mode: 'production'
- }
