

- Each field is validated by the form based on the validation rules specified in the form configuration.
- For more processing, the Form stores validated data in the Vuex shop.

Requirements for Interaction

- At any given moment, the user communicates with just one form sector.
- The submit button is initially secret, as well as when validation fails.
- On the first page load, the first form area appears.
- The completed field vanishes, and a new one emerges.
- The previous-next navigation allows you to navigate all form areas.
- Progress bar that reacts Demonstrates the development of a form.

Let's look at how we should create our own form now that we've figured out what we need.

We'll begin with a simple form that includes a name, an input field, and an error message. A simple structure for a single form field object is shown below.

```
// config/formConfig.json
[
  {
    "type": "text",
    "label": "First Name",
    "name": "firstName",
  },
  ...
]
```

Structure for building forms.

Throughout the process, we'll gradually create this object structure. Now that we have a simple JSON framework, we can start thinking about how we can integrate one or more of the part composition techniques to create our dynamic form. From render functions to a provide/inject pattern, mixins, dynamic modules, and slots, Vue.js has a lot to offer.

Building forms in Vue.js using components

Consider each input field as a Vue component. We use <component> to make fields as specified in the form configuration, and we find the corresponding component based on field-type.
