

Mixins may also include other methods and computed properties.

In the form mixin, an outline of the methods is given.

- `isValid` comes from the computed asset. The `next` and `submit` methods are equivalent, while the `back` approach only reduces the `activeField` index if it is greater than zero.
- `isNext` is set to `true/false` after the `back`, `next`, and `send` methods have been named to ensure that the transformation is guided in the correct direction.

Building forms in Vue.js using Slots

Slots are ideal for distributing and injecting content into kid elements, as well as sorting it into compact chunks. For example, `field-label` is represented by `<label>`, and `field-error` is represented by `<div>` or `<span>`. `<Field-label>` and `<field-error>` are two Vue modules that have slots. To animate or show/hide the error message, we may handle an individual state of the child object.

So far, we've seen `<field-label>`, `<field-error>`, and `<component :is="">`.

To accommodate `<field-label>`, `<field-error>`, and `<component :is="">`, let's construct yet another slotified Vue component `<field-group>`.

`<field-group>` conveniently groups each field with its corresponding children. One of the conditions of the form is that only one area be shown at a time. We can easily display and remove `<field-group>` from the view-port using this classification.

Take a minute to make a rundown of all the roles that the `<form-template>` component should have. For example:

- Importing the form settings
- importing a component each field form has its own set of Vue components.
- assembling all field equipment and
- Completing the form

The above list does not yet contain all of the methods, details, and computed properties needed to communicate with the form.

So, instead of delegating data preparation to a separate component, how about delegating it to a separate component? Since it won't have some markup, the component's sole purpose will be to prepare and provide data to `<form-template>`.

We have a specific way of writing these types of components in Vue.js where models aren't required but functionality is always required. They're also known as Functional Components, and they're one of Vue.js' most important features.
