

Explanation of the code:

For the naming convention of the component name, the 'Pascal case' can be followed. 'FirstTestComponent' is an example of the 'Pascal case' of naming convention. 'Data()' is the function used in the code that returns an object. Every instance of the component receives a different data object, and it need not share the global instance with other instances. In the above code, we have used one method to create a Vue component using template literal. This can be done using the '<script tag>' with 'text/x-template' or using the DOM template.

Single File Components

In large and complex projects, it gets unmanageable to use and manage the global components. 'Single file components' prove helpful in such scenarios. These consist of the single files having .vue as an extension to the name. The file contains three sections including, <template>, <script>, and <style>.

Below is the example component:

```

• <template>
•     <div id = "app">
•         <test1></test1>
•     </div>
• </template>
•
• <script>
• Import test1 from './components/test1.vue'
• Export default {
•     name : 'app',
•     components : { test1 }
• }
• </script>
• <style> </style>

```

Below is the code of the test file imported in above code:

```

• <template>
•     <div>{{ count }}</div>
• </template>
•
• <script>
• Export default {
•     name : 'test1',

```
