

```

•     data() {
•         return {
•             count : 0
•         }
•     }
• }
• </script>
•
• <style> </style>

```

When 'single file components' are used, these components can be directly imported and used within the components as and when required.

Organising Components

Organized Vue Components

It is common for an app to get organised into a 'tree-like structure' with components nested inside.

As an example, there are separate components for the header, main content, and sidebar. Each of them contains more nested components, such as navigation, blogs, etc.

Before using these components, these need to be registered to make Vue aware of them. Component registration is of two types: local and global. Below is the syntax for global type component registration using Vue. component:

```

• Vue.component ('Component Name', {
•     // < options >
• })

```

The global component, once created, can be used within the template in the tree made afterward.
