

```

•         realname : function() {
•             this.name = "John";
•         }
•     }
• });
• var vm = new Vue ({
•     el : '#Test _ Component'
• });
• var vm1 = new Vue ({
•     el : '#Test _ Component1'
• });

```

Below is the code snippet for template that is present in the corresponding js file:

```

• template : '<div v-on : mouseover = "newname()" v-on mouseout = "realname();"> <h1> Component Created with <span id = "name"> {{ name }} </span> </h1> </div>'

```

Output:

Component Created with John

Component Created with John

Explanation of the code:

In the code, we can use the properties of the function as a Vue instance instead of using data as a function. The code contains two methods, namely, 'newname()' and 'realname()'. 'newname()' changes the name property and 'realname()' changes the name back to the original name. 'mouseover' and 'mouseout' are two events. Event 'mouseover' calls the method 'newname()', and event 'mouseout' calls the method 'realname()'.

Passing Data to Components Using Props

Props enable passing data from the parent component to the child component. This helps in creating and using components in smaller chunks to manage specific functionalities. Consider an example of a blog component. The blog component will help display the information, such as author name, comments, and other relevant post details. The component can further be divided into smaller components to handle a specific type of data.
