

```

•     }
•   }
• });

```

Communicating from Child Component to Parent Component Using Event Bus

‘Wrapper methods’ in Vue are helpful in managing the events. These ‘wrapper methods’ get triggered when the selected event occurs. Consider the below example to understand it well:

```

• New Vue ({
•   el : '#app',
•   data() {
•     return {
•       count : 0
•     }
•   },
•   methods : {
•     increment() {
•       this.count++
•     }
•   }
• })

```

Example of template is:

```

• <div id = "app">
•   {{ count }}
•   <div>
•     <button @click = "increment"> + </
button>
•   </div>
• </div>

```

In this code, when the button on click event is selected, the increment method is triggered. In other words, when the button is clicked, the increment method increments the count.

Now, look at the ‘event bus’ to understand how the ‘child component’ communicates with the ‘parent component’. ‘Event buses’ prove very helpful when we want the ‘child component’ to communicate with the ‘parent component’. These work differently than the default function used to com-
