

municate from 'parent component' to 'child component'. 'Event bus' can be used if the application is not large enough to use 'Vuex'.

We will declare count in the 'parent component' and then use it in the 'child component' to use the 'event bus'. It implies that the value of count should increment in the 'child component', and the importance of count should get updated in the 'parent component'.

Below is the code snippet to show the app component:

```
• New Vue ({
•     el : '#app',
•     data() {
•         return {
•             count : 0
•         }
•     }
• })
```

In the 'child component', the value of count gets passed using props, and the 'child component' contains an increment method to increment the value of count. But in our code, consider if we want the 'child component' to only increment the value of count and display the value of count variable in the 'parent component'.

```
• Vue.component('counter', {
•     template : `
•         <div>
•             <button @click =
"increment"> + </button>
•         </div>
•     `,
•     props : {
•         value : {
•             type : Number,
•             required : true
•         }
•     },
•     methods : {
•         increment() {
•             this.count++
•         }
•     }
• })
```

Code snippet for the template:
