

However, when you begin developing large-scale Vue projects, you will encounter certain architectural problems. These are not shortcomings of the framework; rather, they are essential to design choices made by the Vue.js team from time to time. When developing a large scale project, you must first understand precisely what your requirements are. Let's know how you can scale a Vue.js project and make it a success.

Which Routers Should Be Used?

Vue Router is the default Vue.js router. It is fully integrated with the Vue.js core, making it simple to create Single Page Applications with Vue.js. Among the features are:

- Mapping of nested routes and views
- Router configuration that is modular and component-based
- Route parameters, queries, and wildcards
- The transition system in Vue.js is used to power the view transition effects.
- Control over fine-grained navigation
- Links with automatic active CSS classes
- HTML5 history mode or hash mode, with auto-fallback in IE9
- Customizable Scroll Behavior

It is advised to use the official vue-router library for Single Page Applications, which is currently in technical preview.

If you just need any basic routing reasoning, you can do so by manually listening on hashchange and using a dynamic component.

```
<div id="app">
  <component :is="currentView"></component>
</div>
```

```
Vue.component('home', { /* ... */ })
Vue.component('page1', { /* ... */ })
var app = new Vue({
  el: '#app',
  data: {
    currentView: 'home'
  }
})
// Switching pages in your route handler:
app.currentView = 'page1'
```
