

```

• </div>
• </section>
• </div>

```

The target location specified is ``/${movieChoice.id}`` which uses an ES6 template literal to label the target url as the id's of each respective movie. The tag below the target location specified that we want our router-link to render as a list (li) while still listening for click events.

We also need to set up a dynamic router for the Movie component.

```

• const routes = [
•   { path: '/', component: Intro },
•   { path: '/:id', component: Movie }
• ]

```

We've now linked a dynamic element `:id` with the router within the Movie component. This allows us to pick up the different elements within our components using the `$route.params.id`.

We've set up everything that we require for the Movie component. This is what it should look like after all the steps have been followed.

```

• const Movie = {
•   template:
•     `<div>
•       <div class="hero-body">
•         <div class="container has-text-centered">
•           <div class="columns">
•             <div class="column is-half is-offset-one-quarter
vertical-align">
•               <h1 class="home-intro">
•                 {{ selectedMovie.title }}
•               </h1>
•             </div>
•           </div>
•         </div>
•       </div>
•     `
•   data () {
•     return {
•       selectedMovie: movies[this.$route.params.id]
•     }
•   },
•   watch: {

```
