

The distance measurement units are constantly oriented in the direction of the current camera view, allowing you to see the measured distance independent of the camera perspective. The distance measurement units in Architectural units are configured by default. The Ruler preference options allow you to modify the default Ruler settings.

When the system Ruler “object” is chosen, it is shown in green, and the Viewer window shows it is selected by showing `__MOBU SYS RULER PATH__` at the right of the bottom.

A system Ruler path is the “object” of the system Ruler. It is not a model object or an asset. It has no attributes and therefore cannot be accessed through the Navigator Scene or the asset browser, or even in the Schematic view. By clicking the Ruler tool, you may toggle the display of the system Ruler “object” in the scene on and off. The system Ruler “object” is visible in Normal, X-Ray, Models Only, and Models Display Wireframe display modes, depending on what it is snapped to.

Although the system Ruler “object” cannot be saved with the scene, the calculated distance between two objects or components may be saved by turning the system Ruler “object” into a Dimension object. When using the Ruler tool, you cannot reverse your actions. You may, however, change the distance between two objects or components by dragging one of them. When you use the Ruler “object,” standard path HUD components are not shown in the Viewer window.

You may draw a section in the Viewer window using the Ruler tool or use the Ruler tool to calculate the distance between two objects or components in a scene. The Ruler tool allows you to see the measured distance change as you move the objects around. Because deformations are computed on the GPU, the Ruler stays snapped to non-deforming objects.

When you snap a Ruler onto an object that deforms with time, the Ruler unsnaps. If you want the Ruler to stay attached, attach it to an object or element that does not deform over time. In the scenario, there can only be one Ruler. If you wish to add another Ruler to the scene, you must first change or remove the existing Ruler. You may store the calculated distance between two objects or components in a scene as a Dimension object using the Ruler tool.

Nodes

Every 3D object in MotionBuilder is depicted by a rectangular node in the Schematic view. To see the nodes that make up your scene, you need to go to the Schematic view in the Viewer window.
