

Showcasing the positions in a walk cycle

Here is a very brief explanation of the process-

Four essential postures are required for a walk cycle animation. These positions will serve as our visual representation of what occurs in real life. The contact posture is the initial stance. Both feet are on the ground, and the body's weight is distributed evenly between the two legs. Three contact poses are required. In frame 1, the left leg will be forward, on frame 13, the right leg will be forward, and on frame 25, the left leg will be forward again.

The passing position is the second most crucial pose during a stroll. One foot is firmly placed on the ground, while the other is raised. And both feet are preparing to make contact with the following object. Because there are breakdown keys, we've included them here. This is when a walk first begins to exhibit life. It provides variety to our animation exactly amid each phase on frames 7 and 19. We produce a modest sense of gravity and weight by moving up and down between the two positions because the hips are generally a bit higher than they are in contact. The walk's final two stances take everything to the next level.

The up and down postures are what they're called. They characterise the walk's dramatic UP and DOWN moments when the head is at its highest and lowest points. With these positions present, our eyes can easily discern the character's weight. In the down position, the entire body is compressed. On frames 4 and 16, the figure not only reaches his lowest position in vertical space, but he also has a substantial bend in the knee on the planted foot as the hips and spine fall forward. Thus, we obtain the inverse of an extension in the up position. On frames 9 and 22, a stretch to the planted foot is
