

about adding personality and character. Try to keep it very true to what you see in the actual world.

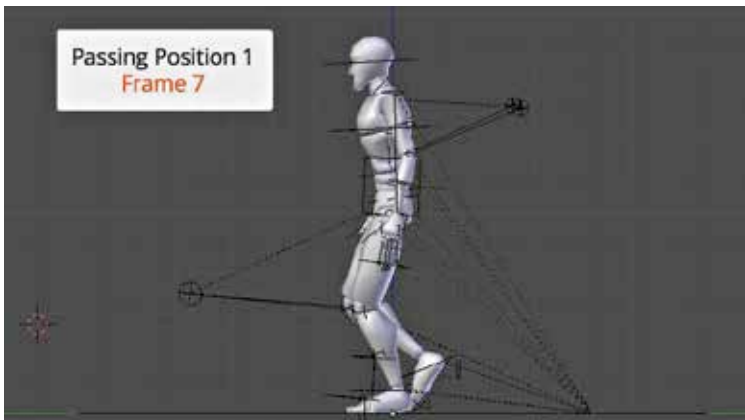

Raising both the head and upper chest somewhat in the down posture is something you should do. Because the lower body drops when the weight is transferred to the contact foot, the upper body will trail somewhat. As a result, the head and chest will be turned back somewhat in the down position to assist in demonstrating this.

Follow the 16th frame and build a downward position for the following phase once you've completed the first down position. Then, copy the characteristics from the initial downward position as per the frame four and paste this on frame 16, making a mirror-image of this posture, as you did earlier.

Creating the Walk Cycle's Passing Position

This position of passing is the following posture, in which the body starts to move upward again, with the rear leg completely above from the ground. In this the knee remains bent. Both of the arms of the characters' should remain at their sides. This is where you'll be in the middle of your stroll. Because his head and chest are now in sync with the rest of his body, you should begin rotating him forward in the passing position.

Because this is a simple walk, you don't need to lift your foot too far off the ground; we as humans like to spend as little energy as possible, so when we walk, we elevate our foot only high enough on the ground so it doesn't contact. Frames 7 and 19 will be used to establish the passing position.

Head and chest sync
