

supposed to. Reference and study are important since our minds subconsciously study the movements of cars or people, and if there is the slightest mistake in creating a walk, then our mind will automatically call it out. With reference, you can achieve a much clearer picture.

2. **Learn to draw**- A little amateur drawing of characters can also go a long way in creating animation. Point out some strong key poses that will help the character to come alive. Planning your animation is a very tough yet crucial job.
3. **Create the Position of Contact** - The position of contact is the foundation for your animation. There are in total four positions, and this is the first position that you need to make and master. The contact position is the beginning and finish of every step, and it determines how defined, and fine your walk will be displayed. The front leg reaches the full length, and the foot makes contact with the ground. The second step is when the rear leg comes in contact with the ground as well, but the heel of the back foot is rising. Don't overextend or have your leg straight. Instead, maintain a small bend in your knees to reduce knee popping. Each leg bears a portion of the body's weight.
4. **Establish the Down Position**- Establishing the down position is the second major position in the walk cycle. Your character's whole weight is transferred to the contacting foot. Because this is the lowest point in the walk, you may use how far the character's hips drop to convey their weight. Make sure you don't go overboard. Keep your character's body up high, so it doesn't bounce up and down too much. The front leg partially blocks the back leg.
5. **Establish a Passing Position** - Establishing a passing posture is the next stance you'll make (or halfway pose). When your character's legs go through the other, this is utilised. As a result, your character's weight will begin to rise in preparation for the passing position. The bodyweight of your character should be on the supporting foot to keep it from seeming unbalanced. The rear foot is now off the ground, but it still points backward at this stage in the walk, putting the character in the middle of the stride. This posture is similar to the first, except the legs now are in the other direction.
6. **Establishing Up Position** - When learning how to animate a walk cycle, the up position is the final of the four primary locations you'll need to know. The character's leg is swinging forward as it prepares to put the foot on the ground at the walk's highest point. The character's weight
