

scripts, and several other elements, animators create wonders in designing such as VFX, 3D, video games, etc.

In this chapter, we are going to discuss three important elements of animation, i.e.

- Loops
- Clips
- Importing from 3D Max

Let's first talk about what a loop is. Just like in programming, a loop means a sequence of instructions (routines or subroutines) set that is repeated constantly until the desired result is met. The loop allows you to continuously execute the same code multiple times, without defining the function or setting the same animation every time.

A scene in animation is an event occurring between characters, during a specific time period in a single place that unfolds the story from inception to climax. A scene occurs in a loop. It can have single or multiple loops, where each of them contains different actions, so when you run it in the animation, it looks like one whole part.

Prepare a Scene

## Creating a Loop

In order to create a loop in animation, you need to go through multiple steps. Every program that runs animation needs an animation loop to perform simulation at regular intervals.
