

you have the animation states of the whole body on the first layer, including standing, sitting, and walking. Now, if you want to make the character wave, there are two options. First is creating the animation states again wherein the character is waving the hand. The second and better option is to use an additive layer. Using the additive layer, you need to animate an arm of the character and add the animation layers on the top and import it. That will fulfill your purpose without affecting the underlying animation.

How to Create an Additive Layer:

To create an additive layer, open the Animation Layer Editor. Click on New Layer Button to add a new layer, which gets added as an additive layer by default.

Adding a Duplicate Layer:

You can also create a duplicate layer by duplicating the already existing layer. You can perform it by selecting the layer that you want to duplicate and then click on the button for the Duplicate Layer. Alternatively, you can simply copy and paste as well to create a duplicate layer.

2. Override Layer

In the override layer, the animation layer overrides another animation layer where the properties of the two layers are the same. As an example, you have an animation of a character in a space marine. The character is running towards its target with the rifle in hand. Now you want to change the pace of the character; so, instead of running, he/she should be progressing slowly. To add this change in the animation, you need to use the override layer, which also helps to retain the Original Animation.

Adding an Override Layer

1. Open the Action Layer Panel and click on Add Override layer. The override layer gets added above the selected layer.
2. Reset the character to the Original Position.
3. Select the parts of the model to animate. In this example, these would be legs and lower body parts of the model.
