Animating Faces

Animating faces is an area in graphics that contains the methods and different techniques to generate and animate images of the character's face, which can be of a human, an animal, a humanoid, any legendary character, or an emoticon. Human faces play a crucial role as regards verbal or non-verbal communication and are responsible for the interest of science, technology, and artists in the animation of faces. That is because the expressions on the face help in determining the feelings inside. These facial expressions only make the character believable or decide if the character will engage the audience. Keyframing is the primary technique used to generate animation data. Facial animation finds its applications primarily in communication, computer games, education, films, scientific simulations, etc.

Animating Faces Workflows

Below are the workflows while animating the Character:

1. Facial Keyframing Workflow

It is a method that keyframes the custom expressions to create facial animation.

Below is the workflow to create facial animation:

- Load a model with cluster shapes or shapes
- Insert character face to the scene
