

- Define custom expressions in the character face settings
- Navigate to the character face animation pane and select the expressions and change the values. Now, set the keyframes to complete the animation of the face model.

2. Facial Motion Capture Workflow

Facial motion capture means the conversion of movements made by a person's face to a digital database that gets used to create computer animation for games, movies, and real-time avatars. The database contains the coordinates of the reference points locating the actor's face. The capture can be two- or three-dimensional; the two-dimensional capture is done using capture software or a single camera, whereas the three-dimensional capture is done using laser marker or multi-camera rigs. The capture of facial motion is similar to the body motion but is more complicated, as compared to body movement, because of the high resolution needed to track the small movements of lips and eyes, which are less than a few millimeters. The facial motion capture workflow is the process to animate the head model while capturing the motion capture data. Here, the actor's face gets used for mapping the character's face and the motion data.

3. Audio-driven Facial Animation Workflow

This workflow uses the voice device along with the character's face and makes the character talk using the audio file as its voice. The expressions to show on the face of the character are done using the voice device.
