

nemes required by the character to convey through an audio file.

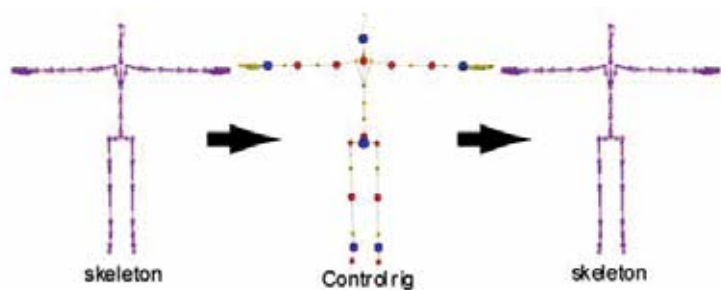

- Add the character face into the scene and then add custom expressions for every phoneme from the Character Face Definition Pane. Now, map the phoneme shapes to the custom expressions.
- Add the audio file and connect the character face and voice device.
- Add the sound parameter using the settings option of the voice device added.

Plots in Animation

Once the animation gets created, it needs to be plotted. The plotting in animation is also called transferring or baking because it involves the transfer of animations in the scene to the model selected. If you have animation in multiple layers, you can plot by merging the layers into the base layer. The number of keyframes to be added while plotting can be determined using Smart Plot, thus simplifying the editing required for plotted animation.

How to Plot Animation

The plotting in animation can occur from multiple areas that can be a character, face settings of the character, and the actor's face. For example, when you try to plot a character, you click on the Settings of Character that opens the character dialog box. Using this dialog box, you can create the control rig. Control rigs are the node-based system used by animators to create dynamic and flexible characters having user-friendly interfaces.

Plots using Control Rig

The animation data is usually present as the skeleton form. Hence, the control rig needs to be created first. Once the animation on the control rig is completed, the animation needs to be plotted back to the skeleton. Thus, the model data is ready to export as a package. To use the control rig, you
