

cycle for a “walk and run,” it is necessary to create the cycle with the start and end walk cycle and then the walk and turn cycle. Each of these cycles gets triggered itself before the triggered motion clip gets triggered. Thus, the walk cycle occurs in a loop until the trigger of a “walk and turn” cycle.

Trigger sequence

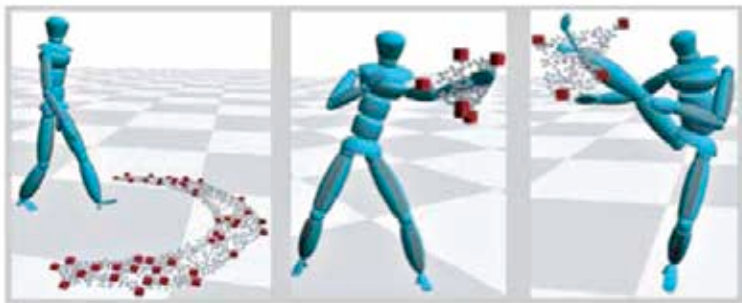

The trigger sequence consists of a set of motion cycles. A series of motion cycles can occur in the trigger sequence, and the first motion cycle in the sequence is the base motion cycle. When more motion clips get used in the trigger sequence along with the different types of animation and run cycles, it is better to use multiple motion cycles.

To understand it, consider another example with motion clips for walking, running, and walking backward. This trigger sequence has three base cycles, viz. walk, run, and walk backward. The walk cycle (A), run cycle (B), and walking backward cycle (C) are the three base cycles. Another simple way to form the animation cycle is using the story window as motion clips and then plot to the character and save each cycle as a different .fbx file.
