

games were played in sequence. When the first act ends, the second act starts irrespective of the fact that the action is cyclic or fire-and-forget. One cycle has to end before another starts. However, with the introduction of the concept of blending, the transition of character from one state to another can be made to look natural. Blending means combining more than two animations and creating a new animation with this blend. Blending allows blending two or more takes of one character to make a new take. It also allows blending the different parts of the same scene and creating an animation cycle to get used in the Trigger window. The timings of the takes can also get altered to match the pace of different movements for different takes.

Creating Blending Object

To create a blending object, drag the object to work upon into the empty track. The blending object can be the node selection with data captures or a complete hierarchy of plotted data. The blending object will appear in the form of a white line, which represents the animation data used to blend. The blend can be standard, local, pose, or interpolation. The blending object can be changed anytime by simply dragging the sensors or objects to the empty area.

Conclusion

The chapter extensively discusses keyframing in animation. Keyframing is the concept that is used to add motion to the characters in the images. Animation is all about manipulating the image and making it look as the characters in the image are in motion. **d**
