

animations through motion capture software or tools. Some Hollywood train-themed holiday movies show the best use of MoCap.

The cameras used by motion capturing systems have motion sensors. The captured data is then equipped with motion capture software. A virtual skeleton is created that moves just like the actors in real-time.

As per the actor's performance, the production team and director can record and watch the animations. Once the desired performance is achieved, the characters are then animated in real-time.

Working of Motion Capture/MoCap Tool

MoCap tools or applications use light reflection to record movement. The actor's movements are recorded, and the actor has to wear a special suit that is covered with reflective dots. The lit-up cameras here record the repetitive movements of the actor. These captured moments of the actors are then transmitted to the 3D animation skeleton.

If the light on a certain area gets blocked, then the animated part gets blocked, thereby resulting in animators not identifying and relating those actions. In such a scenario, the technicians clean the footage and let the software know what should happen with those markers or actions.

When motion capture was launched, there were only a few people who could use it perfectly. Even the tool's worth was around tens of thousands of dollars. The users also have to establish a proper studio to prepare the character animations.
