

However, now there are numerous free-of-cost software available, and few others can be bought at the cost of a DSLR. Rokoko is one such software tool that can be used to shoot animation. Users can buy the full suite of the software and create their animations. The free version of Rokoko is also available.

Nevertheless, the users need the full suite to record and create their animations. There are also pre-recorded animations that can be downloaded and used to make the perfect animations without spending too much time recording and animating the characters.

Step-by-step working of MotionBuilder tool

Setup

To use the software, you should first download the appropriate version of the tool from the Autodesk site. There are several compatible versions available for download. Once downloaded, install the software. You can download it for Windows or Linux operating systems and accordingly install the appropriate version of the tool.

The characters that you want to model have to be brought into MotionBuilder and characterised as well. Before creating the character animation and control rig, some more poses have to be created using other animation tools. You can even define and characterise the model's skeleton template as well.

Motion Sources

There is usually a single-step interoperability feature where the data can be exchanged between MotionBuilder, Maya, Softimage, and 3ds Max. For this, you will have to connect the MotionBuilder with the target source. By doing so, the scene, data, or images can be exchanged in-between the applications.

The large animated applications usually include one or more smaller components of third-party apps. In MotionBuilder, there is a command on the File menu that can be used to import the images from other applications. In case the target application does not get installed in your system, then you won't be able to see them on the submenu.

After finalising your character, you can then choose the motion source to animate it. You can follow the below-mentioned steps to animate the character:

1. First, double click the characterised character to select it.
2. Now you can use the menu for character settings.
