

2) Portray and file yourself

If you don't want to spend time noticing other people's movements, then you can record your movements while doing certain regular tasks. The recording of your actions will help you in defining the animation movement.

We all constantly have cameras with us; it's there in our pockets always. So, instead of looking and recording other's movements, why not record your actions, get out of your seat, and look at your actions?

Act according to the scene and record your movement. It may look somewhat awkward, but this recording can give your essential starting blocks. You can record and watch the videos and re-record the missed ones as well.

3) Form the key poses

Many big moments involve small movements as well. To capture any big pose, you need not follow and notice every small step in detail; however, try to identify some of the keyframes or major steps that are not visible in the big picture.

Choose the big moment that can work as keyframes. If you keep on working on the small areas and ignore the large ones, then you may miss the keyframes. Hence, the movement may not look natural as well. In the first layer, try to pose some of the specific and keyframes only with a good timing sense; later, you can add more frames as well.

4) Start with an eye capture

With every specific movement, certain eye movements are associated. A specific sequence of eye movement is always associated with human motion or movements. Since the eyes move freely in any direction wherever they want to go, the head follows them and then the neck; this process continues as per the body movement. Mostly, when we look at someone, our body is the first part that moves.

5) Proper handling of gravity effect

It is quite obvious that there is some effect of gravity on our every movement. Whenever anyone walks or moves, the movements are mostly dictated by our physical build. Lightweight, tall and thin people have less weight on their feet, and the people with more weight may have heavier footfall. This may look simple, but you should always be careful while defining the weight distribution on the animation.
