

Specifying the “Up Vector”

- Choose the light from the assets listed by the Scene Browser.
- To assign an Up Vector to the light, you need to Alt-drag a marker from the Viewer window to the Property window’s Light Settings Up Vector field.

Spot Light

Among all the available light types, Spot light possesses the highest number of settings. Unlike their counterparts, they can project images and give fogging effects. Moreover, you can specify the Cone Angle. You can also customize the behaviour and look of Spot lights by projecting the light onto the ground, projecting images, showing the light beam, etc.

Spot lights can be customized in multiple ways.

Light Settings

Whenever you select a light, you can view its settings in the “Light Settings” window. By default, you will be able to see Global light in this window. In order to modify the settings of other lights in your scene, you need to select that light in the Viewer window or Scene Browser. With the help of Light Settings, you can illuminate models and other objects in your scene according to your requirements.

Global Light

Despite the absence of lights in your scene, when you add an object, you will be able to see it. This is because of the presence of “Global light”, a default light that illuminates your scene even when you have not added any light. However, unlike other lights, you will not be able to select it or make any modification. The global light settings can only be used to change the parameters like fog settings and the overall lighting effects.

Shaders

Shaders determine how the surface of a model or an object interacts with
