

the lighting in the scene. This, in turn, gives rise to effects like specularity, transparency, colour creation, reflection, and refraction.

In Autodesk MotionBuilder, one can use shaders to add various kinds of effects to their models. Different types of shaders can dictate how a surface reacts to light. Additionally, they can also be used to give rise to special effects such as bump mapping and cartoon outlines. To select the shader that you want to add to a scene, you need to browse the Shaders folder. To see the effect of a particular shader on an object, you need to drag the shader and drop it on the object.

Shaders control the way in which the surface of an object responds to the lighting in the scene.

## Effects

There are different shading effects in Autodesk MotionBuilder. This gives users the liberty of selecting the one that suits their project. Some of the most commonly used effects are listed below.

- **Cartoon look:** While shaders are generally utilized to make models appear more realistic, you can also use cartoon-style shaders to give your objects a cartoon-like look. When this effect is applied to a 3D model, it outlines its form and flattens its colour depth, giving rise to a two-dimensional appearance.
- **Reflection:** With the help of this effect, you can effectively distinguish objects made of different substances. Although these shaders cause your objects to reflect elements in their vicinity, these effects are not just confined to creating reflective surfaces. They can be combined with other effects to give rise to different looks. For example, when a reflection shader is combined with a dark material, it results in a brushed steel texture.
