

MotionBuilder Render Window

Rendering Quality

As rendering creates a realistic 3D image, if the rendering specifications are meticulously set to coincide with nature, then the quality of the image can be generated as photorealistic. To make the quality of the final render great, some aspects need to be taken care of

1. **Colour movement-** One major angle of the 3D rendering process usually ignored is the colour management technique and exposure. Without proper colour management, commonly known as linear rendering, the rendered images from the engines comprehend scene lighting accurately, but the image displayed on your monitor will be different. To display the correct picture, one should use different colour spaces for rendering image display and stock of images.
2. **Anti- Aliasing-** This gets rid of any rough edges in the rendering image. Anti-aliasing helps in making the image more realistic and professional. Without this, the sharp ends in the boundary will look uneven and not set in with nature.
3. **Exposure-** To set the perfect lighting element in the rendering image is important. The image. Exposure means the duration of time a camera's film is on the light. The image will be brighter if the film is exposed for a longer time to light. While using CG, the registered light values are often offset to create long or short exposures. Exposure or lighting can be easily corrected using the color management process.
4. **Motion Blur-** While capturing some pictures from a camera, some images might turn up to be a blur, especially while capturing images
