

- **Bootloader Configuration Files:** From the configuration file, you will have to remove read and write permissions to apply the password to boot-specific operating systems. This should be done to all users but not the root file. You can successfully change these permissions to **700** for the file.
- **System and Daemon Configuration Files:** You should restrict the user to edit the contents of daemon configuration files and restrict the system rights. It is advisable not to restrict the read permissions. However, you should remove the write permissions. For this, you can change the rights to **644**.
- **Firewall Scripts:** You cannot restrict the users from reading the firewall file. However, it is recommended not to allow them to write the file. For such cases, the root user can automatically run the firewall script on boot. You can align the **700** permissions as not all users would need the rights.

File Access

We have already placed limits on what users could do in this chaotic multi-user world. However, what about the information they have access to? Every file, after all, does have permissions as well as an owner. The owner
