

Wizards of the Internet

Every single website or web service or even the back-end of your favourite video game lies somewhere in the midst of a massive data centre. And in this era of the Internet, 78.6 per cent of web servers out there are built using a Unix based operating system. Linux is by far, the most popular Unix based operating system and the vast majority of that happens to be Debian based distros. We've picked Ubuntu Server 20.04 LTS as our server OS of choice. It's beginner-friendly and every cloud service provider such as Google Cloud, Microsoft Azure, Amazon Web Services, etc. will give you the choice of setting up a server instance using Ubuntu. That's our way of saying that this little booklet is going to open your eyes to how 78.6 per cent of the web servers in the world work, and to some extent, the websites that are hosted on them.

Setting up a server and administering it is a full-time job. Every data centre out there has a couple of server administrators working on-site at all times. It's a demanding job but it also pays quite well. While you don't necessarily have to make a career out of it, we can certainly help you get started with understanding all the aspects of setting up a web server and then managing it properly. If you do plan to set up your own website or perhaps want to develop an app, then knowing the basics of administering a server instance goes a long way in easing your development process. With practically every application out there having an online component, you'll end up learning these things anyway. So why not start now?
