Process Management

Process Management in Linux is a way to streamline, organise and analyse the entire code, to work through it more efficiently.

A process in Linux is a program put into execution. The data and instructions set in a program are read and used to give an output. Simply put, when you give your Linux machine a command, it starts a new process. Here, we shall cover the basics of process management in Linux, the different functions, and what you can do with those. Linux is referred to as a preemptive multitasking
