Running a code in Linux

Various States of a Process in Linux

Once you understand how to execute a process, monitor and analyze it depending on different circumstances; you need to understand the other states that Linux works in:

1. **Running:** The process here is either running (the current process in the system) or ready to run. This means that it's waiting to be assigned to one of the processors.
2. **Waiting:** The next is the waiting stage, wherein a process is waiting for an event to occur. The two different waiting stages are interruptible (processes that can be interrupted by signals) and uninterruptible processes (that can't be interrupted by any signal).
3. **Stopped:** Here, the process has been stopped by receiving a signal. For instance, a process is debugged or similar examples.
4. **Zombie:** At this stage, a process is dead or paused but can still enter the process table again.

How to Examine Processes Running on Linux

After the types of commands to view active listings, you need to understand how to examine a process with the system monitor. Each command that is mentioned and studies gives a different view, with a range of details available. Moreover, a series and combinations of commands can help you with
