

```
$ top  
$ sudo top  
$ sudo top [options]
```

3. **Glances:** This command has a lot of advanced features when it comes to monitoring.
4. **Ps-fu:** With the ps-fu command, you see a lot more data than ps-ef. This is major because the process details are also included.
5. **Top and ntop:** These two commands will help you get an idea of the most active processes or processes using the most resources. This also allows you to reorder your program view depending on your preferred criteria.
6. **/proc:** The following helpful directory here is /proc, which has a considerable amount of information available. You need to use this multiple times to understand the details available directly. It provides a view of process details used in the system currently.

Conclusion

In all, Linux Process Management is used to instruct the computer to work. Creating foreground and background processes and assigning them to the correct command is crucial for efficient management. Now that the various aspects of process management in Linux have been discussed, you can easily handle, manage, and monitor your processes and programs.
