

Introduction

When using Linux, you may need to handle hard disks, portable media such as USB drives and SD cards, and other items. This is particularly important if you want to dual-boot with Windows or another Linux installation.

This is why it's critical to understand how to manage your disks and the partitions that reside on them. Some of the things you can perform using Ubuntu's Disk Utility include resizing a partition, reformatting your hard disk, and monitoring its health. Let's talk more about disk management on Ubuntu.

Adjusting

A filesystem may be expanded to make use of the space left over after partitioning. This is often feasible even when the filesystem is mounted. It may be reduced according to the spare space inside it to create room for another partition following the filesystem. Not all filesystems allow resizing. The filesystem size and partition size are adjusted in tandem. In the same vein, how is a partition resized without a filesystem?

Open Disks from the Activities overview to resize a filesystem/partition.

From the list of storage devices on the left, choose the disk holding the filesystem in question. If the drive has more than one volume, choose the one that contains the filesystem.

Click the menu button in the toolbar under the Volumes section. Then, if there is no filesystem, select "Resize Filesystem" or "Resize".

A dialog box will appear in which the new size may be selected. The filesystem will be mounted in order to determine the minimum size based on the quantity of current content. If shrinking is not supported, the current size is the minimal size. When reducing the filesystem, provide enough space for it to function quickly and reliably.

Filesystem resizing may take longer depending on how much data must be transferred from the smaller portion.

Automatic file system resizing necessitates filesystem repair. Thus, it is recommended that critical data be backed up before proceeding. If the activity is interrupted, the filesystem will be damaged.

By clicking Resize, you confirm that you want to initiate the operation.

If resizing a mounted filesystem is not supported, the operation will unmount the filesystem. Please be patient while the filesystem gets resized.

The filesystem is available to use again once the necessary resizing and repair actions are completed.
