

A server administrator

Linux system administrators wear many hats. The smaller the environment, the more hats the administrator has to wear. But, the most critical areas that need their services are application installation, security management, and automation. In other words, a system administrator has to cover every aspect of software and hardware management, i.e., both for virtual and physical systems.

Administrators need to have the technical know-how in the fields of database, network security, firewalls, and other aspects of working networks. It is an essential requirement for solving complex issues. The primary objective of this chapter is to teach you about minimum system requirements to install Ubuntu Linux Server, installation steps for Ubuntu server, popular Linux distros, pros and cons of each distro, etc.

Minimum System Requirements:

Ubuntu 20.04 Server Edition is built to run on extremely lean hardware and can scale up to run on massive servers with hundreds of CPU cores, terabytes of RAM and super fast network lines. Since we're looking at the latest version of the Ubuntu Server OS, the bare minimum requirements have evolved a little but it is still lean.
