

```
$ sudo systemctl status apache2
```

Step 3: Check the Firewall Settings

The installation will get complete with the required permissions and then as the next step, you will have to check the firewall settings. If not, then you may have to enable the firewall settings for the Apache web server.

Step 4: Enabling, Setting, and Verifying Firewall Changes

Once the installation gets completed, you will have to adjust the settings of the firewall only then HTTP traffic will be allowed. UFW command allows Apache traffic on two ports one is through Port 80 and the other Port 443.

However, there are multiple UFW profiles that you can use to accomplish the step. You can check the currently available profiles through the following command:

```
$ sudo ufw app list
```

The following command can be used as the terminal command to redirect the traffic on specific ports:

```
$ sudo ufw allow 'Apache Full'
```

```
younis@younis-VirtualBox:~$ sudo ufw allow 'Apache Full'
[sudo] password for younis:
Rules updated
Rules updated (v6)
younis@younis-VirtualBox:~$
```

The change in settings can be verified through the following command:

```
$ sudo ufw status
```

```
younis@younis-VirtualBox:~$ sudo ufw status
Status: active
