Step 5: Check the Status of Apache

You can now check whether the Apache is working perfectly or not on your system by just opening the web browser on your machine and in a new tab type *http://10.0.2.15*

IP address (here you may have to replace the IP with your machine IP address).

Setting Up the Virtual Host

After installing the Apache service, it is time to set up the virtual host. The installed Apache server can be used to host the sites. Apache has a default virtual host already installed on the server. If you want to host a single website then you will have to upload only its configuration file in the following manner:

To upload a single file, you need to upload the required file under the "/var/*www/html*" directory. Path for the file can be defined in the following manner:

```
Path=/etc/apache2/sites-enabled/000-default.conf
```

Virtual Host Set Up

Resultantly, a new file will be opened in gedit editor.

Domain Name Creation

To host multiple sites on a single domain name server, you will have to use another command. Moreover, you will have to create a new virtual host configuration file first for all websites that you want to host. Here, we have
