

In this way, if the following figure appears in the browser for the specified URL, then it does mean that the Apache server is working perfectly.

MySQL Installation

The web server is now successfully installed. You now have to install the database system to gain accessibility to the files for your site. What might be better than My SQL for this purpose? It is a widely used database management system that has PHP integration.

Make use of the following:

```
$ sudo apt install mysql-server
```

Verify installation by hitting the Y key followed by ENTER when prompted. Post-installation, it is recommended that you run a security script that has been included as a pre-installation on MySQL. This phase will assist you in eliminating any vulnerabilities in your database system.

```
$ sudo MySQL_secure_installation
```

It brings us to the issue of Validation.

You have to use the VALIDATE PASSWORD PLUGIN to verify and increase the security of your passwords. It confirms the password's strength and allows users to create only sufficiently safe passwords. Would you like to add a VALIDATE PASSWORD plugin to your website?

Press y|Y for "Yes," any other key for "No":

If you answer yes, the code will prompt you to choose a degree of password validation.

Once the validation is complete, you may test the MySQL login processor by:

```
$ sudo mysql
```

To exit, type:

```
mysql> exit
```

MySQL Testing

Mysql does not permit the usage of user root for password authentication by default, as it uses the auth socket authentication technique. Therefore, we may either modify the authentication mechanism for a root or create a new user that uses the mysql native password technique.

Therefore, run the following command to establish a new user and test mysql access.
