This will install both the required packages on your system. When the installation gets finished you can now check and confirm the installation through the following command:

```
$ php –v
```

After doing this, your PHP component will be configured perfectly; however, before that, you can test your setup with a PHP script. Therefore, in our next step, we will be testing the PHP installation as well.

Testing PHP Processing on the Web Server

Now that you have set up your virtual host and PHP files, ensure to check the handling of process requests and PHP files. You can do this through the following steps:

i) Creation of new info.php file inside your custom webroot folder:

```
$ nano /var/www/your _ domain/info.php
```

This command will open a blank file. You will have to add the following valid PHP code in that file:

```
<?php
```

Php Page
