

```
phpinfo();
```

After completing the process of file creation, you can save and close the file. The script then can be checked from the web browser by accessing the IP address and domain name of the file followed by the script name. For this example, we have kept the script name as `info.php`:

```
http://server _ domain _ or _ IP/info.php
```

A page will appear on the screen like shown in the image on the previous page. The page will have all information about the server from a PHP perspective. The page also makes sure that on your system both PHP and Apache are working perfectly.

Removal of “info.php” file

However, you can delete the file instantly when you see the settings as the file contains sensitive information about your Ubuntu server and PHP environment. The following command helps you do so:

```
$sudo rm /var/www/your _ domain/info.php
```

Nevertheless, the page can always be recreated if required.

Conclusion

In this installation guide, we have learned to set up Apache server and PHP on the Ubuntu platform. The server can host multiple sites at the same time. You can use Apache as the web server and PHP as the platform to display the information fetched from the server. After installation of the server, you should also ensure that the connection is completely secured by serving [HTTPS](#) requests.
