

going to be quite slow and rough if you want to preview the whole video, so it makes sense to dial the resolution down a notch or few (half, quarter, etc.), so you can do a quick preview at a lower quality and once you're completely done, you can dial it up again and view it at full resolution.

It's important to keep in mind how the timeline is structured again. It's just like a graph on a functional level. The quicker you understand this, the lesser complications you will have later on. The vertical axis is the Y – coordinate. In AE, that's the depth factor essentially. The lower the layer, the further back and deeper it is and the further up it is, the likelier it's going to be at the top of the composition. And the X-axis is the time factor. The more to the left a bar is, the sooner it's going to come into the fray and the more to the right it is, the later it's going to get involved. Similarly, the longer a bar is in length, the longer it's going to stay on screen! If there are too many layers in the timeline panel, all you need to do is scroll the mouse wheel or use the scroll bars at the bottom for time and on the right for depth.

2) The Composition panel

In this panel, we can see that hovering over elements, shows a box surrounding it. If you want to select a particular object, all you need to do is click on it and it will simultaneously select the object in the timeline panel too.

1. Magnifier tool 2. Resolution Scaler 3. Grids and Guides 4. Preview time elapsed

The first box in the bottom left of the composition panel is the magnification tool with a range of size options including 'Fit' (to the panel outline). We can use this to zoom in and zoom out based on our requirements.
