

keyframe in the timeline panel. The ripple effect of this is that our transitions look much more fluid rather than moving in a very block like and staggered manner. Compared to normal keyframing, it makes more sense to use this wherever possible. A normal keyframe is usually denoted by a diamond in the timeline panel. An eased keyframe on the other hand, is marked by an hour glass figure (a small one) in the timeline panel to differentiate it from the normal keyframe. To create some dynamic movements, many keyframes are added to the same property in one sequence (like the moon waning and waxing)

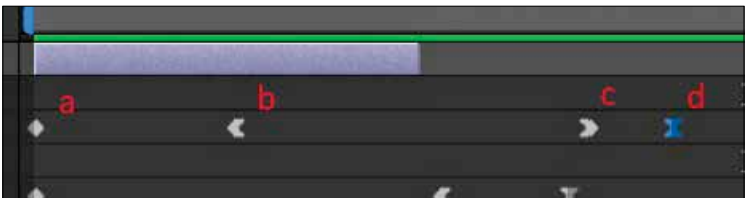

- The graph editor in the timeline panel can be used to see how smooth an effect is. Normal keyframes usually have straight lines. An eased keyframe has a more parabolic appearance in the graph editor.

The graph editor symbol and the associated graphs.

There are 4 different types of keyframes:

- Linear Keyframe** – These are the ones that are used by default, they create a rigid movement and are not smooth as we have already seen.
- Ease out Keyframe** – This is used at the starting of an effect. It is used to create a smooth transition into the effect. It's called 'Ease out' as it eases out of the keyframe (which is a marker for an effect in simple terms, and not the effect itself). There is a small delay in the beginning to achieve this.
- Ease In Keyframe** – This is used at the end of an effect. Similar to the Ease out effect, this is also used to create a smooth transition. The only difference is that it achieves the same purpose while transitioning out of an effect, i.e. 'Eases into' a keyframe. This is done by incorporating a small delay at the end of an effect.

a. Linear keyframe b. Ease out keyframe c. Ease in keyframe d. Easy ease keyframe
