

The Path we made earlier and the Path properties

When a path is applied to an object, we get a new set of keyframes in the object's property time bar called 'Rove keyframes' which are circular in shape. Once these are applied, the bird has to not just move head first but it also has to rotate according to the path. To do this, set up keyframes at all the vertex points and at the in between points, add some keyframes with modified rotation values. Once these are done, make sure to add ease out and ease in keyframes and convert the intermediate keyframes to easy ease keyframes.

Similarly, shapes can also be used as animation paths for objects. For example, if you want to show an athlete running around a track. First you need to make an ellipse that mimics the track shape, then scroll down to the path information under Contents → (Shape name) → (Shape name) Path 1. Right click this and click 'Convert to Bezier Path). Followed by the same steps as above, select both the path properties, copy it, expand the properties of the objects that you want to give a path and then paste the copied properties in its position property. Essentially, you just need to unlock the path info of an element to do this.

*TIP 1: Press 'R' to Toggle the Rotation property*

*TIP 2: Press 'U' to show all properties with a keyframe. *
