

- **Maximum security and privacy**

Another leading benefit of blockchain is its security and privacy as it does not include any intermediary, which minimises the chances of fraud or theft. Blockchain builds an unaltered ledger that provides all the transactions with end-to-end encryption, shutting doors to suspicious activities. Additionally, the data is never stored in a single computer; it is spread across a network of computers, eliminating the chances of unauthorised activities such as hacking.

- **Reduced cost**

Blockchain is a decentralised structure, which means no involvement of a third party. This reduces manual tasks as well as promotes cost-saving activities.

- **Speed**

Another big advantage of blockchain is its speed. As there are no intermediaries and fewer manual interventions, blockchain promotes much faster and more reliable transactions than conventional methods. It is recorded that blockchain can complete transactions within a fraction of seconds. However, the speed majorly depends upon various factors, such as network traffic. However, experts believe blockchain can easily beat traditional methods of making transactions.

- **Individual control of data**

In a world where data plays a significant role, technology like blockchain is a blessing in disguise. It allows individuals to have complete control over data that belongs to them. Individuals and institutions have the power to decide with whom and for how long they want to share a piece of information or want to keep it confidential.

- **Visibility and traceability**

Blockchain not only manages speed but also helps manage inventory, confirms the history, and responds to problems within time. Experts believe that blockchain can easily track the origins of various items, including organic items and machines.

- **Immutability**

Once the transaction is recorded on the blockchain, there is no way it can be
