

changed or removed or tampered with. Blockchain promotes time-spammed and data-spammed transactions, which means there's a permanent record of everything happening, making it a secure and reliable network to carry out transactions.

● Innovation

The last in our list of blockchain benefits is innovation, as leaders from multiple industries consider blockchain to trace and solve the existing problems, which improves the outcome.

How Blockchain works

Each block in the blockchain mainly contains three things:

1. Data
2. The hash of the block
3. The previous block's hash

There are different types of blockchains, and the data stored inside each block is highly dependent on the type of blockchain it is. The bitcoin blockchain stores the details about the transaction here, including “the sender,” “the receiver,” and most importantly, “the number of coins that have been transacted.” Any decentralised database that numerous participants have managed is known as distributed ledger technology or DLT.

Similarly, blockchain is a type of DLT as it is managed by several participants in which transactions are recorded with a rigid cryptographic signature popularly known as “hash.” You can compare the hash to a fingerprint
