

means that you cannot have more than seven GPUs connected on such a motherboard.

6 GPU + Integrated GPU on the motherboard = 7 GPU

Integrated GPU on the motherboard is always counted as one GPU.

Make sure that your motherboard's integrated GPU is set up as your main target display or main video output. In this way, you will be able to remove the stress of mining GPUs for producing video output. In the motherboard BIOS settings, you are required to set the PCIOE to IGFX.

It is not advisable to use PCI-E splitters as it is not going to work. The main reason behind this is that the motherboard caps are connected to GPU lanes.

If you have a motherboard that has Molex PSU or SATA connectors, then you are required to make them connected to the PSU. For instance, H81 pro-BTC has two Molex connectors and they must be connected to a PSU if you are planning to have four or more GPUs connected.

How to set up the motherboard on your PC?

Refer to the steps given below to set up the motherboard on your PC in just a few minutes:

The first step is to connect your motherboard with the Disk, RAM, and CPU. Do not use any GPU until this step is completed.

- The next step is to connect your video display to the motherboard's integrated GPU.
- Now, turn on your PC and go into the motherboard BIOS
- Set up your chipsets primary video display to IGFX (Integrated GPU)
- Set up PCI-E to auto
- Discard the audio
- If you have a 4G option under your motherboard then activate it. This option is available only in some motherboards that are used in optimising your PC if it has more than 4 GPUs connected.
- Set the power loss option to always be on. It ensures that your PC will turn on immediately after it is connected to its power source.

How to set other PC parts?

RAM

- For six GPU rigs, 4GB RAM is considered enough.
- For 12 or 13 GPU rigs, 8GB RAM is considered enough.
